Chapter 1:
Introduction

1.1 Purpose of the Report

The purpose of a AI based vehicle accident alert system using ESP 32 WROVER, GSM SIM, power supply, sensors like Gyroscope, Accelerometer, GPS and GSM for communication to provide an automated solution for detecting and reporting vehicle accidents promptly. The system's key components work together to perform the following tasks:

1. Accident Detection:

Sensors attached to the ESP32 WROVER detect sudden impacts or abnormal movements that indicate a possible accident.

2. Location Tracking:

The GPS module gathers real-time location data, identifying the precise location where the accident occurred.

3. Alert Transmission:

The GSM SIM module sends an alert message to pre-configured contacts (such as emergency services, family members, or a control center) that includes details about the accident and the GPS coordinates.

The system aims to reduce response times in emergencies by quickly alerting relevant authorities or individuals, potentially saving lives by ensuring rapid assistance.

1.2 Background

The concept of an AI based vehicle accident alert system using microcontrollers like ESP32 WROVER has emerged from the growing need for road safety solutions in response to increasing vehicle accidents worldwide. With the rise in traffic density and high-speed transportation, road accidents have become a significant concern, leading to severe injuries and fatalities. Traditional accident response methods often rely on human intervention, which can result in delays in reporting incidents and getting timely assistance, especially in remote areas where witnesses may not be available.

To address this issue, automated accident detection systems are being developed to enhance the speed and efficiency of emergency responses. By integrating sensors such as accelerometers, gyroscopes, and vibration detectors, these systems can accurately detect accidents in real-time. Additionally, AI algorithms help analyze sensor data, reducing false alarms and improving detection accuracy. With GPS and GSM modules, accident locations can be instantly transmitted to emergency services, minimizing response time and increasing survival rates. Such intelligent systems are crucial for modern transportation safety, aiding in rapid intervention and reducing casualties.

1.3 Problem Statement

Here are some potential problem statements for a AI based vehicle accident alert system using ESP32 WROVER, GSM SIM, Sensors and GPS:

1. Delayed Emergency Response in Accidents:

Many accidents, especially in remote or low-traffic areas, go unreported for a significant amount of time due to a lack of immediate communication. This delay in notifying emergency services can lead to increased fatalities and more severe injuries, as victims may not receive medical attention quickly enough.

2. Insufficient Real-Time Communication:

Real-time communication between the accident site and emergency services is crucial. Many systems lack the ability to immediately alert key contacts or emergency responders with relevant details such as accident severity and location. This gap in communication prevents timely assistance.

By addressing these problems, the proposed accident alert system aims to provide an automated, real-time solution that enhances the speed, accuracy, and efficiency of emergency responses, particularly for drivers in need of urgent help after a crash.

1.4 Project Scope

The project focuses on designing, developing, and implementing a AI based vehicle accident alert system using ESP32 WROVER, GSM SIM, Sensors and GPS technology. The system aims to automatically detect vehicle accidents and instantly send alert messages to predefined emergency contacts with the exact location of the incident. Below is a detailed breakdown of the project scope:

1. **Objective:**
   - To create a cost-effective, real-time accident detection and alert system that can be integrated into various types of vehicles.
   - To ensure rapid notification of emergency responders or family members through automatic SMS alerts containing the vehicle's GPS coordinates when an accident occurs.

2. **System Components:**
   - ESP32 WROVER: The microcontroller will act as the central processing unit, managing all sensor inputs and controlling the communication modules.
   - GSM SIM Module: This module will be used to send text messages (SMS) and a call to emergency contacts when an accident is detected.
   - GPS Module: The system will include a GPS module to provide accurate real-time location information, which will be embedded in the alert message.
   - Sensors (e.g. gyroscope, accelerometers, vibration sensors): To detect sudden impacts, vibrations, or abnormal movements that signal an accident.

3. **System Functions:**
   - Accident Detection: The system will continuously monitor the vehicle’s motion through sensors. Upon detecting a sudden impact or a significant change in motion, it will assume an accident has occurred.
   - Location Tracking: Using the GPS module, the system will identify and store the real-time location (latitude and longitude) of the vehicle at the time of the accident.
   - Real-Time Alerting: Once an accident is detected, the system will use the GSM module to send a message to pre-configured emergency contacts. The message will include the GPS coordinates of the accident location, allowing emergency services or family members to respond quickly.

4. Key Features:

- Real-time accident detection using sensors and microcontrollers.
- Automated emergency alerts sent via GSM technology to a list of pre-configured contacts.
- Precise GPS location tracking for accurate and immediate accident site identification.
- Low-cost implementation, making it accessible for a wide range of vehicles, including older or budget models.
- Scalability to integrate additional features such as user feedback, accident severity analysis, or cloud-based storage for accident records.

5. Project Deliverables:

- A functional prototype of the accident alert system using ESP32 WROVER, GSM, Sensors and GPS.
- A detailed report and schematic of the system, including circuit diagrams, code, and system architecture.
- Testing and Validation: The system will be tested for accuracy in detecting accidents and for timely communication of location data in various real-world conditions.
- User Manual: Documentation on how to configure and operate the system, including troubleshooting guidelines.

6. Limitations:

- Signal Dependency: The effectiveness of the GSM and GPS modules will depend on network availability and GPS signal strength, which might be compromised in remote or obstructed areas (e.g., tunnels, mountainous regions).
- Power Source: The system will need to be powered by the vehicle's battery, which could be a limitation in some scenarios if the battery fails during or after an accident.

7. Future Enhancements:

- Integration with vehicle diagnostics to assess accident severity based on internal sensor data (e.g., airbag deployment).
- Expansion of communication options, including integration with mobile applications or cloud services.
- Adding accident prevention features, such as real-time vehicle speed monitoring, fatigue detection, or collision warning systems.
- Adding Human health monitoring to ensure severity in the accident occurred.

8. Target Audience:

- The system is designed for drivers, vehicle owners, and transportation companies who want an affordable safety solution to improve accident response times.
- It can be deployed in private cars, taxis, motorcycles, and even commercial or industrial vehicles, enhancing safety across various transportation sectors.In short can be used in any vehicle having USB port.

In summary, this project seeks to create a reliable, AI based vehicle accident alert system that enhances road safety and provides timely assistance during accidents, reducing response times and potentially saving lives.

Chapter 2:

Literature Survey for Problem Identification

2.1 Literature Survey

Introduction:

A literature survey provides an overview of previous studies, technologies, and systems related to real-time accident detection and alert systems. In recent years, several advancements in microcontrollers, GSM technology, Sensors and GPS modules have been applied to the field of vehicle safety. This survey reviews the key contributions, methods, and solutions offered by various researchers and developers in this domain.

1. Accident Detection and Notification Systems

Numerous studies have focused on developing automatic accident detection systems using a combination of sensors, microcontrollers, and communication modules. These systems are designed to detect accidents based on sudden deceleration, impact forces, and vibrations, which are key indicators of collisions.

- S. Dinesh et al. (2017) developed an accident detection and alert system using an Arduino microcontroller, GSM, and GPS. Their system was able to send real-time location data to emergency contacts when an accident was detected. They highlighted the importance of using GPS to pinpoint the exact location, significantly reducing the time taken for emergency responders to reach the site.
- U. K. Singh and D. S. Kushwaha (2016) created a GSM and GPS-based vehicle accident detection system. Their work focused on using an accelerometer to detect sudden vehicle movements and vibrations, which triggered the alert system. The research emphasized the system's ability to function even in remote areas where conventional communication may be limited.

2. Sensor-Based Detection Systems

Various sensor technologies have been integrated into accident alert systems to improve accuracy in detecting vehicle collisions.

- K. P. S. Kumar et al. (2014) implemented a system using MEMS accelerometers to detect the impact of collisions. The system used a microcontroller to process the sensor data and trigger an emergency alert when a critical impact threshold was crossed. The authors also explored the use of GSM technology to send SMS notifications to emergency services.
- H. S. Jadhav and A. Kadam (2015) introduced a system that used both an accelerometer and a vibration sensor for accident detection. The dual-sensor approach reduced the number of false positives in detecting accidents (e.g., sudden braking or rough road conditions). Their findings suggested that multi-sensor systems improve accuracy in accident detection.

3. GSM and GPS-Based Alert Systems

The integration of GSM and GPS technology into accident detection systems has proven to be effective in sending timely alerts with accurate location data.

- S. Rajan and R. Kavya (2015) focused on developing a system that utilized a GSM SIM 900A module to send SMS alerts to emergency contacts, while the GPS module provided real-time location data. Their research highlighted the low-cost and high efficiency of using GSM-based communication, especially in regions with good mobile network coverage.
- R. A. Malik and M. Khan (2019) implemented a AI based vehicle accident alert system using GSM and GPS, where the location and accident details were sent to emergency services and family members. Their work also introduced the idea of geofencing, where alerts are sent only when the accident occurs outside a certain safe zone, minimizing false alarms in non-critical situations.

4. Microcontroller-Based Systems (Arduino and Others)

Microcontrollers, particularly Arduino, have become popular in the development of low-cost accident alert systems due to their ease of use and wide availability.

- A. D. Yadav and P. P. Dahikar (2018) designed an accident detection system using ESP32 WROVER. Their system combined sensors for impact detection with a GSM module for sending alerts. The authors emphasized the flexibility of the Arduino platform, allowing users to easily modify the system based on specific vehicle types and user requirements.
- N. K. Rao et al. (2016) used ESP32 WROVER to control a system that could detect accidents and automatically send GPS coordinates via SMS. They further proposed the possibility of linking the system with IoT platforms to store accident data in a cloud for future analysis.

5. Real-Time Monitoring and Emergency Response

The effectiveness of real-time monitoring and the immediate transmission of accident information is a critical element in saving lives.

- S. Sharma et al. (2020) demonstrated the effectiveness of real-time accident detection by developing a system that used both GPS and GSM to send real-time location details to first responders. Their study highlighted the benefits of combining real-time monitoring with automated alert systems, which reduce the delay in emergency services responding to accidents.

6. Challenges and Future Directions

Several researchers have also identified challenges in implementing these systems effectively. The main challenges include:

- False Positives: Many systems still struggle with detecting false positives (e.g., sudden braking or rough terrain), which can trigger unnecessary alerts.
- Network Dependence: GSM and GPS systems are reliant on network availability, which may not be reliable in remote or rural areas, potentially limiting the system's effectiveness.
- Power Consumption: The continuous operation of GPS and GSM modules requires power from the vehicle's battery, which could be a limitation in long-term applications.

Future research directions suggest the integration of machine learning algorithms for accident detection, improving the system’s ability to differentiate between real accidents and non-critical events. Additionally, the use of cloud services and IoT-based systems could provide centralized accident reporting platforms for faster, more coordinated emergency responses

2.2 CPM (Critical Path Method)

CPM stands for Critical Path Method, which is a project planning and management technique. Here's a simple explanation:

CPM helps you plan and schedule tasks in a project. It identifies the "critical path," which is the sequence of tasks that, if delayed, will make the project take longer. These tasks are like the backbone of your project schedule.

With CPM, you create a timeline, and each task is like a building block in that timeline. You figure out how long each task will take and which tasks depend on others. This helps you see the order in which tasks need to be done.

CPM also calculates the earliest start and finish times for each task, as well as the latest start and finish times without delaying the project. This flexibility helps you manage your project's timeline effectively.

In a nutshell, CPM is a tool that helps you understand the most critical tasks in your project, how they're connected, and how long the project will take. It's great for keeping your project on track and making sure it finishes on time.

2.3 Project Network

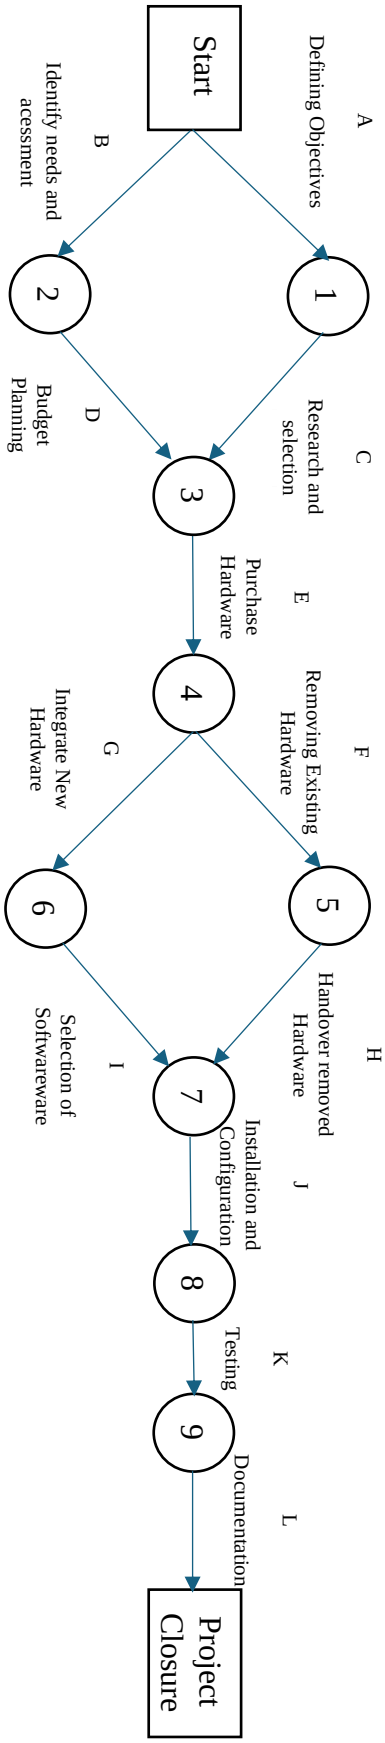

Fig:2.3 Project Network

2.4 Gantt Table

Task name	Microtasks	Parallel Tasks	Duration (days)	Dependencies
A. Defining Objectives	We are trying to achieve improved safety and faster emergency response by modernizing accident-prone vehicles.	A, B	2	
B. Identify Need and Assessment	The current system has limitations that hinder efficient accident detection and emergency response.	A, B	2	
C. Research and Selection	Identify solution, evaluate, and select wireless communication technology, hardware components, and software options for the project.	C, D	5	A, B
D. Budget Planning	Develop a budget for the project.	C, D	5	A, B
E. Purchase Hardware	Order and receive the hardware components for the Project.		5	C, D
F. Remove Existing Hardware	Remove the existing hardware from the board & program new hardware if required	F, G	3	E
G. Integrate New Hardware	Install and connect the new hardware components.	F, G	3	F
H. Handover Removed Hardware	Deliver the removed hardware to the appropriate department.	H, I	2	F
I. Select Software	Choose the software that will be used to control and operate the new circuit.	H, I	2	C, D
J. Install and Configure Software	Install and configure the software on the project.		5	E, G, I
K. Testing	Test the functioning of all the components to ensure that it meets all requirements.		5	J
L. Documentation	Write documentation for the project, including instructions on how to use and maintain it.		10	J, K
Project Closure	Close the project and hand over the circuit.		1	L

Table 2.4: Gantt Table

2.5 PDCA cycle for a whole project

The PDCA cycle (Plan-Do-Check-Act), also known as the Deming Cycle, is a continuous improvement model used to enhance processes and solve problems. It can be applied to the development and implementation of a AI based vehicle accident alert system using ESP32 WROVER, GSM, and GPS. Here's how the PDCA cycle can be structured for this project:

1. Plan:

In this phase, the objective is to clearly define the goals, identify the resources required, and outline the processes for system development.

- *Problem Identification:*
  - Recognize the need for a AI based vehicle accident alert system to reduce the delay in emergency responses during vehicle accidents.

- *Objectives:*
  - Develop a cost-effective system that can detect accidents and send automated alerts to emergency contacts with precise GPS location data.
  - Reduce response time for emergency services after an accident.

- *System Design & Planning:*
  - Hardware Requirements: ESP32 WROVER, GSM module, GPS module, sensors (gyroscope, accelerometers, vibration sensors), power supply.
  - Software Requirements: Programming for accident detection, GPS location acquisition, and GSM communication.
  - System Features: Real-time accident detection, GPS-based location tracking, automated SMS alerts, and minimal false positives.
  - Risk Identification: Network signal dependency (GSM/GPS), power limitations from the vehicle's battery.

- *Success Criteria:*
  - Accurate accident detection.
  - Real-time transmission of alert messages.
  - Reliable performance under various driving and environmental conditions.

2. Do:

This phase involves the execution of the planned activities, where the system is developed, integrated, and tested.

- *Prototype Development:*
  - Design and assemble the accident alert system using the selected components (ESP32 WROVER, GSM, GPS, and sensors).
  - Develop the code for integrating sensors to detect collisions and control communication via GSM and GPS.

- *Test Environment Setup:*
  - Conduct initial tests to ensure that all components are working as expected.
  - Configure GSM and GPS modules to send SMS with location data when an accident is detected.

- *Implementation of Core Functions:*
  - Sensor integration: Collect and process data from accelerometers or vibration sensors.
  - Alert system: Automatically send a text message with GPS coordinates using GSM upon detecting an accident.

- *Initial Testing:*
  - Perform basic tests to check if the system accurately detects collisions.
  - Ensure that the GPS module collects accurate location data.
  - Validate that the GSM module successfully sends SMS alerts to the pre-configured contacts.

3. Check:

In this phase, the system's performance is monitored, and data is collected to evaluate how well the system meets its objectives.

- *System Testing & Validation:*
  - Test Scenarios:
    - Simulate accidents under various conditions (e.g., different vehicle speeds, terrains, and types of impact).
    - Monitor system behavior in both urban areas (good signal reception) and remote areas (weak GSM/GPS signals).
    - Data Collection:
    - Track system accuracy: Evaluate how effectively the sensors detect true accidents and avoid false positives.
    - Assess the accuracy of GPS data in identifying the location of the accident.
    - Measure the time taken from accident detection to sending an alert (real-time communication).

- *Result Evaluation:*
  - Analyze the effectiveness of the system in sending alerts and location details within a reasonable time frame.
  - Identify any weaknesses, such as instances where the system failed to detect an accident or sent incorrect information.
  - Review battery usage and performance over long-term use.

- *Feedback Gathering:*
  - Collect feedback from stakeholders, such as potential users (e.g., drivers or emergency service providers), to assess usability and reliability.

4. Act:

In this final phase, necessary improvements are made based on the results from the "Check" phase. The aim is to optimize the system for better performance.

- *System Refinement:*
  - Address False Positives: Adjust the sensitivity of the accelerometer and vibration sensors to minimize false triggers (e.g., sudden braking or speed bumps).
  - Improve GPS Accuracy: Calibrate the GPS module to ensure precise location tracking, especially in areas with weak signals.
  - Optimize Power Usage: Implement power-saving techniques to reduce the system's battery consumption, such as putting modules in low-power mode when not in use.
  - Enhance Alert System: Add features like accident severity estimation based on sensor data, or introduce a delay mechanism to avoid sending false alerts during non-critical situations.

- *Retesting:*
  - Perform additional tests to validate the system improvements.
  - Ensure that the changes address the issues identified during the "Check" phase and enhance overall system performance.

- *Deployment:*
  - After successful testing, deploy the refined system in real-world environments (e.g., in different vehicle types and driving conditions).

- *Continuous Monitoring & Updates:*
  - Continuously monitor the system's performance post-deployment.
  - Gather feedback and data for ongoing improvements, ensuring the system remains effective and up-to-date with the latest technologies.

Conclusion:
By following the PDCA cycle, the AI based vehicle accident alert system will undergo a structured process of planning, development, testing, and refinement. This ensures continuous improvement, leading to a reliable and efficient system that can help save lives by providing timely accident alerts.

Chapter 3:
Detailed Methodology

3.1 Methodology

The methodology for developing an AI based vehicle accident alert system using ESP32 WROVER, GSM SIM, sensors, and GPS involves several key steps to ensure accurate accident detection and efficient emergency response.

1. **System Design & Hardware Selection**
    - Selection of ESP32 WROVER as the main microcontroller for processing.
    - Integration of MPU6050 accelerometer and gyroscope for motion and impact detection.
    - Use of SW-420 vibration sensor to detect sudden impacts.
    - Deployment of MAX9814 sound sensor to monitor accident noise levels.
    - Implementation of a GPS module for real-time location tracking.
    - GSM SIM module for emergency SMS alerts.
2. **Sensor Data Collection & Preprocessing**
    - Sensors continuously monitor acceleration, vibration, sound, and gyroscope data.
    - Data is filtered and normalized to remove noise and improve accuracy.
    - Threshold values for accident detection are established through testing.
3. **AI Model for Accident Detection**
    - Machine learning-based model trained using past accident datasets.
    - Model compares real-time sensor data with trained patterns.
    - AI algorithm identifies abnormal movements, vibrations, and sounds associated with accidents.
4. **Real-Time Accident Detection & Alert Mechanism**
    - When an accident is detected, the system verifies the severity based on sensor readings.
    - GPS coordinates are fetched to determine the exact accident location.
    - An emergency alert message with location details is sent to predefined contacts and emergency services via GSM.
5. **Data Logging & Analysis**
    - Sensor data and accident occurrences are stored in an SD card for future analysis.
    - Insights from recorded data help refine the AI model for better accuracy.
6. **Testing & Optimization**
    - The system is tested in various accident scenarios to ensure reliability.
    - Calibration and optimization of AI model thresholds for minimizing false alerts.
    - Performance evaluation based on response time, accuracy, and real-world conditions.

By following this structured methodology, the system ensures rapid accident detection and automated emergency alerts, enhancing road safety and reducing response time for critical accidents.

3.2 System Details

3.1.1 Block Diagram Explanation

The block diagram illustrates the functional components and interconnections of the AI based vehicle accident alert system. The system is centered around the ESP32-WROVER-B, which acts as the main processing unit, collecting data from multiple sensors and communicating with external modules for accident detection and alert transmission.

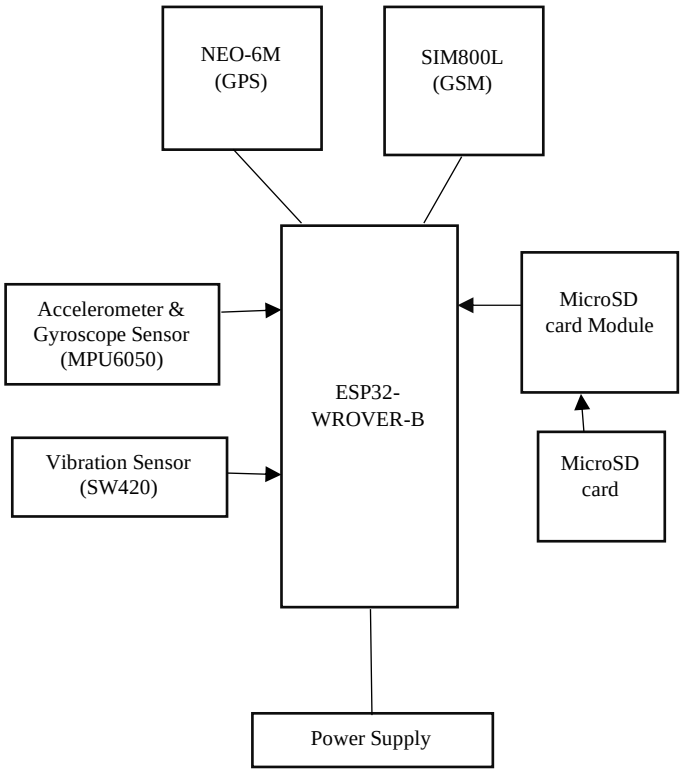

Figure 3.1: System Block Diagram

Working Summary:

1. The sensors continuously monitor vehicle movement, vibrations, and sound levels.
2. The ESP32 processes sensor data and compares it with the trained AI model stored in the MicroSD card.
3. If an accident is detected, the GPS module provides location details.
4. The GSM module sends an emergency SMS with accident details to relevant authorities and contacts.

1. ESP32-WROVER-B (Microcontroller Unit)

- The ESP32-WROVER-B serves as the central control unit, interfacing with all sensors and modules.
- It processes real-time sensor data and runs a machine learning AI model stored in a MicroSD card to enhance accident detection accuracy.
- Upon confirming an accident, it triggers emergency communication via the GSM module.

2. Sensors for Accident Detection

- MPU6050 (Accelerometer & Gyroscope): Detects sudden changes in acceleration and orientation, which indicate a potential crash.
- SW-420 (Vibration/Crash Sensor): Detects strong vibrations caused by collisions.
- MAX9814 (Electret Microphone Sound Sensor – Not shown in diagram): Captures loud crash sounds to further validate an accident.

3. GPS Module (NEO-6M)

- Determines the real-time location of the vehicle.
- Provides latitude and longitude coordinates, which are included in the emergency alert message.

4. GSM Module (SIM800L)

- Sends an emergency SMS alert to nearby hospitals, police stations, and pre-saved emergency contacts.
- The message includes accident details and GPS location for quick response.

5. MicroSD Card Module

- Stores the pre-trained AI model used to compare real-time sensor data with previous accident data.
- Enhances the accuracy of accident detection by reducing false alarms.

6. Power Supply

- Provides necessary voltage and current to all components, ensuring stable operation of the system.

3.1.2 Working Principle

The AI based vehicle accident alert system is designed to detect vehicular accidents with high accuracy and send emergency alerts to nearby hospitals, saved emergency contacts, and the police station. The system is built around the ESP32-WROVER microcontroller, which serves as the central processing unit, interfacing with multiple sensors and communication modules.

- *Accident Detection Mechanism:*

The system employs a combination of three primary sensors to ensure precise accident detection:

1. MPU6050 – Accelerometer & Gyroscope Sensor:
   - Detects sudden impact and abrupt orientation changes of the vehicle, indicating a potential crash.
2. SW-420 Vibration Sensor:
   - Identifies strong vibrations caused by collisions or rollovers.
3. MAX9814 Electret Microphone Sound Sensor:
   - Captures loud crash sounds, providing an additional validation layer for accident detection.

- *AI-Based Accuracy Enhancement:*

To improve the accuracy of accident detection, a Machine Learning AI model is implemented. The AI is trained with pre-collected accident data and is stored on a MicroSD card. The real-time sensor readings are compared with the trained AI model to distinguish actual accidents from false positives (such as sudden braking or minor bumps).

- *Emergency Alert Communication:*

Once an accident is confirmed, the system triggers an emergency response using the following communication modules:

1. NEO-6M GPS Module:
   - Determines the precise location of the accident.
2. GSM Module:
   - Sends an automated emergency SMS containing the accident location and status to:
     - Nearby hospitals
     - Saved emergency contacts
     - The police station

The system ensures a fast and reliable emergency response, potentially saving lives by reducing the time taken for medical assistance to reach the accident site.

3.3 Hardware Components & Description

The Descriptive function of each component and Microcontroller in the AI based accident alert system is given below

3.3.1 ESP32-WROVER-B (Microcontroller Unit)

The ESP32-WROVER-B serves as the central processing unit in the AI based vehicle accident alert system, integrating various sensors, communication modules, and AI-based decision-making to ensure real-time accident detection and emergency response. Its primary function is to collect, process, and analyze data, make intelligent decisions, and trigger alerts when an accident is detected.

➢ *Central Control & Data Processing*

- The ESP32-WROVER-B acts as the main controller, executing all critical operations of the system.
- It continuously reads input data from multiple sensors and processes the raw signals **to** detect anomalies indicating an accident**.**
- Uses edge computing capabilities to analyze patterns and decide whether an accident has occurred, reducing dependency on external servers.

➢ *AI-Based Decision Making*

- The microcontroller runs a pre-trained AI model stored in its flash memory or SD card to classify real-time sensor data**.**
- It compares live data with trained accident patterns, filtering out false positives and preventing unnecessary alerts.
- If accident conditions are met, ESP32-WROVER-B triggers the emergency alert system immediately.

➢ *Real-Time Communication & Alert Transmission*

- The ESP32 controls the GSM module to send SMS alerts with the accident location to predefined emergency contacts.
- It fetches GPS coordinates from the GPS module and formats them into a message before transmission.
- Uses UART communication to send emergency alerts while ensuring reliable data transfer.

➢ *Data Logging & Storage Management*

- Stores accident-related data on an SD card for future analysis and AI model improvements.
- Maintains a log of sensor readings, timestamps, and GPS locations for validation and research.

➢ *System Optimization & Power Management*

- Utilizes low-power modes to ensure efficient energy consumption, especially in battery-powered applications.
- Executes multitasking operations using its dual-core architecture to manage data acquisition, processing, and communication simultaneously.
- Handles real-time interrupts for immediate response when an accident is detected.

Conclusion

The ESP32-WROVER-B serves as the intelligent core of the system, efficiently handling sensor integration, AI-based accident detection, and real-time communication. Its ability to process data locally, make intelligent decisions, and send emergency alerts instantly ensures a robust, reliable, and life-saving accident alert system.

3.3.2 NEO-6M (GPS Module)

The NEO-6M GPS module plays a crucial role in the AI based vehicle accident alert system by providing accurate location data that is essential for emergency response services. It ensures that the accident site is identified in real time, allowing authorities and emergency contacts to reach the affected vehicle without delays.

➢ *Real-Time Location Tracking*

- Continuously acquires GPS signals from multiple satellites and determines the precise latitude and longitude of the vehicle.
- Updates location data at regular intervals to ensure accurate tracking.
- Ensures that the system maintains a stable and reliable GPS signal, even in challenging environments (e.g., tunnels, urban areas).

➢ *Immediate Accident Location Retrieval*

- As soon as the ESP32-WROVER-B detects an accident, it requests location data from the NEO-6M GPS module.
- The GPS module instantly provides the last known coordinates, allowing the system to send an emergency alert with the exact accident location.
- Helps authorities pinpoint the crash site quickly, reducing emergency response time.

➢ *GPS Data Communication with Microcontroller (ESP32-WROVER-B)*

- Communicates with ESP32-WROVER-B using the UART (Universal Asynchronous Receiver-Transmitter) protocol.
- Transmits GPS location data in the form of NMEA (National Marine Electronics Association) sentences, containing detailed information such as:
    - Latitude and Longitude (accident location)
    - Altitude (useful for identifying accidents in hilly regions)

➢ *Integration with GSM Module for Emergency Alerts*

- Once an accident is confirmed, the ESP32-WROVER-B retrieves the GPS coordinates from the NEO-6M module.
- These coordinates are formatted into a text message and sent via the GSM module to predefined emergency contacts.
- Ensures that first responders receive an accurate, real-time location, increasing the chances of survivability for accident victims.

➢ *Location Data Logging for Analysis & AI Model Training*

- The ESP32 stores GPS location history on the SD card for post-accident analysis.
- This data can be used for machine learning model improvements, identifying high-risk accident zones, and improving overall road safety measures.

➢ *Low Power Consumption & Efficient Operation*

- The NEO-6M GPS module is designed to operate with low power consumption, making it ideal for continuous tracking without draining the power supply.
- Uses power-saving modes to ensure energy efficiency when the system is in standby mode.

Conclusion

The NEO-6M GPS module is a critical component of the AI based vehicle accident alert system, providing real-time, accurate location tracking that enables emergency responders to reach accident sites quickly and efficiently. Its integration with ESP32-WROVER-B and the GSM module ensures that accident alerts are sent immediately with precise coordinates**,** reducing emergency response times and potentially saving lives.

3.3.3 SIM800L (GSM Module)

The SIM800L GSM module is a crucial component of the AI based vehicle accident alert system, responsible for wireless communication and emergency alert transmission. It enables the system to send real-time accident notifications via SMS and, if required, make emergency calls to predefined contacts. By utilizing cellular networks, the module ensures that accident alerts are delivered instantly, regardless of the location of the vehicle.

➢ *Real-Time Emergency Alert Transmission*

When an accident is detected based on sensor data (MPU6050 accelerometer, vibration, and sound sensors), the ESP32-WROVER-B microcontroller immediately triggers the SIM800L GSM module to send an emergency alert.

The GSM module transmits a predefined SMS containing:

- "Accident Detected!" Notification: Alerts emergency contacts about the accident.
- Real-Time GPS Location: Fetched from the NEO-6M GPS module, ensuring accurate location tracking.
- Time and Date Stamp: Provides the exact moment of the accident.

This SMS is sent to emergency responders, family members, and relevant authorities, ensuring a rapid response.

➢ *Automated Emergency Calls for Critical Situations*

In addition to SMS alerts, the SIM800L module can be programmed to initiate an emergency call when an accident is detected. This function is particularly useful in cases where immediate human intervention is needed.

- The module dials the emergency contact number stored in the system.
- If the call is not answered, the system can be configured **to** retry calling multiple numbers until a response is received.
- If a responder answers, they can attempt to **communicate with the victim** and assess the severity of the situation.

This feature significantly improves the chances of timely medical assistance, especially in severe accidents where the victim may be unconscious and unable to call for help.

➢ *Network Connectivity and Communication with ESP32*

The SIM800L module communicates with the ESP32 microcontroller using UART (Universal Asynchronous Receiver-Transmitter) communication, ensuring smooth transmission of messages and calls.

- AT Commands: The ESP32 sends AT commands to the SIM800L module to execute SMS and call operations.
- SMS Format: The ESP32 formats the accident alert message and transmits it through the SIM800L module.
- Error Handling: If the GSM signal is weak or unavailable, the system attempts multiple retries to ensure message delivery.

The SIM800L module supports 2G networks, making it highly reliable for low-power, long-distance communication in remote areas where high-speed internet is unavailable.

➢ *Continuous Monitoring and Network Availability Check*

To ensure reliable communication, the SIM800L module is programmed to:

- Check network connectivity at regular intervals**.**
- Reconnect automatically in case of network loss.
- Indicate signal strength to the ESP32 microcontroller, allowing for alternative communication methods if GSM signals are weak.

This feature ensures uninterrupted connectivity, reducing the chances of failed emergency alerts due to network issues.

➢ *Power Efficiency and Low Energy Consumption*

The SIM800L module is designed to operate on low power consumption, making it suitable for continuous operation in battery-powered systems. Key features include:

- Sleep Mode: Reduces power consumption when the system is idle.
- Efficient Signal Processing: Ensures messages and calls are sent with minimal energy usage.
- Automatic Wake-Up on Accident Detection: Activates only when an accident occurs, optimizing power efficiency.

This ensures that the system remains **operational for extended periods** without significant battery drain.

Conclusion

The SIM800L GSM module is an essential component of the AI based vehicle accident alert system, enabling instant emergency communication through SMS alerts and automated calls. By integrating real-time GPS data, continuous network monitoring, and power-efficient operation, the system ensures that accident victims receive timely assistance, significantly improving their chances of survival.

This module plays a critical role in transforming accident response mechanisms by eliminating manual reporting delays and providing automated, real-time emergency alerts.

3.3.4 MPU6050 (Accelerometer & Gyroscope Sensor)

The MPU6050 is a 6-axis motion tracking sensor that includes a 3-axis accelerometer and a 3 axis gyroscope. In the AI based vehicle accident alert system, this sensor plays a crucial role in detecting vehicle accidents by continuously monitoring motion, acceleration, and angular velocity.

➢ *Real-Time Motion and Impact Detection*

The MPU6050 sensor helps in detecting sudden changes in acceleration and orientation, which are strong indicators of an accident.

- The accelerometer measures linear acceleration (changes in speed or sudden stops), allowing the system to detect strong impacts or crashes.
- The gyroscope tracks angular velocity, which helps determine if the vehicle has flipped, rolled over, or experienced unusual movements.

By continuously analyzing acceleration and rotation data, the system can identify whether an accident has occurred.

➢ *Threshold-Based Accident Detection Algorithm*

To accurately detect an accident, the ESP32-WROVER-B microcontroller processes data from the MPU6050 using a predefined threshold algorithm:

- If acceleration values (X, Y, Z axes) exceed a critical threshold (e.g., a sudden deceleration from 60 km/h to 0 km/h in milliseconds), an accident is suspected.
- If gyro readings indicate rapid rotation or an unnatural tilt (such as a rollover beyond 90°), the system confirms the accident.
- The system filters out false positives caused by sudden braking or sharp turns by comparing acceleration and rotation patterns.

Once the data confirms an accident, the ESP32 microcontroller triggers the emergency alert mechanism, sending a distress signal via the SIM800L GSM module with the vehicle's GPS location.

➢ *Monitoring Vehicle Stability and Driver Behavior*

Apart from accident detection, the MPU6050 helps in analyzing vehicle stability and driver behavior, which can be used for preventive safety measures.

- Detects harsh braking, rapid acceleration, and aggressive cornering, providing insights into reckless driving.
- Monitors suspicious movements that indicate loss of control, such as skidding or swerving.
- Logs driving patterns, which can be used for driver safety evaluations.

This feature is especially useful for fleet management, insurance companies, and driver safety analysis.

➢ *Integration with Other Sensors for Accurate Decision-Making*

The MPU6050 sensor works alongside other sensors in the system to improve accident detection accuracy:

- Vibration Sensor (SW-420): Helps confirm whether an accident has occurred based on impact force.
- Sound Sensor (MAX9814): Detects unusual noises (such as crashes or sudden loud bangs) for additional verification.
- GPS Module (NEO-6M): Provides real-time location data for emergency responders.

By combining inputs from these sensors, the system ensures that alerts are triggered only in actual accident scenarios, reducing false alarms.

➢ *Power Efficiency and Continuous Monitoring*

The MPU6050 sensor operates on low power, making it suitable for continuous monitoring without excessive battery drain.

- Uses sleep mode when the vehicle is idle to conserve power.
- Activates automatically when motion is detected.
- Ensures long-term operation, making it reliable for vehicle safety applications.

Conclusion

The MPU6050 (Accelerometer & Gyroscope Sensor) is a key component in the AI based vehicle accident alert system, responsible for detecting crashes, rollovers, and sudden impacts with high accuracy. By analyzing motion data in real time, integrating with other sensors, and leveraging AI-based learning models, it ensures that emergency alerts are sent instantly when an accident occurs**.**

3.3.5 SW-420 (Vibration / Crash Sensor)

The SW-420 Vibration Sensor plays a crucial role in detecting strong impacts or collisions in the AI based vehicle accident alert system. This sensor is designed to sense vibrations, shocks, or sudden jerks caused by an accident and provide a signal to the microcontroller (ESP32-WROVER-B).

➢ *Accident Detection Through Vibration Analysis*

- The SW-420 sensor consists of a spring-based mechanism that gets activated when an impact force exceeds a certain threshold.
- If a vehicle collides with another object, overturns, or experiences a sudden impact, the vibration sensor detects the shock and sends a high signal (logic 1) to the microcontroller.
- The microcontroller then processes this signal to determine whether an accident has occurred.

➢ *Integration with Other Sensors for Improved Accuracy*

- The vibration sensor works in combination with the MPU6050 (Accelerometer & Gyroscope) to differentiate between minor road bumps and actual collisions.
- If the MPU6050 detects unusual acceleration and angular velocity changes along with a high vibration signal from the SW-420, the system confirms an accident.

➢ *Triggering the Emergency Alert System*

- Once an accident is confirmed based on vibration levels and acceleration data, the ESP32 microcontroller sends a trigger signal to the SIM800L GSM module.
- This initiates an emergency SMS containing the GPS location (from the NEO-6M module) to predefined contacts and emergency services.

➢ *Sensitivity Adjustment for Different Road Conditions*

- The SW-420 sensor allows sensitivity adjustment based on the type of vehicle and road conditions.
- This ensures that the system remains reliable in different environments, from highway driving to off-road conditions, without unnecessary false triggers.

➢ *Power-Efficient and Continuous Monitoring*

- The SW-420 operates on low power, ensuring continuous monitoring without draining the battery.
- The microcontroller can configure the sensor to enter sleep mode when the vehicle is stationary, further optimizing power consumption.

Conclusion

The SW-420 Vibration / Crash Sensor serves as a critical component in the accident alert system by detecting strong impacts and sudden shocks. When combined with other sensors like the MPU6050 (Accelerometer & Gyroscope) and NEO-6M GPS module, it ensures highly accurate accident detection while minimizing false alarms. By instantly notifying emergency responders, the system improves road safety and reduces fatalities caused by delayed medical assistance.

3.3.6 MAX9814 (Electret Microphone Sound Sensor)

The MAX9814 Electret Microphone Sound Sensor is a key component in the AI based vehicle accident alert system, designed to detect high-intensity sounds associated with accidents, such as vehicle collisions, tire screeches, and airbag deployments. By analyzing sound levels, the system improves accident detection accuracy and enhances the emergency response process.

➢ *Detecting High-Intensity Sounds in Accidents*

- The MAX9814 is equipped with an Automatic Gain Control (AGC) amplifier, allowing it to automatically adjust its sensitivity and detect sudden loud noises effectively.
- In an accident scenario, the sensor captures sounds such as:
  - Metal impact from vehicle collisions
  - Tire screeches during sudden braking
  - Airbag deployment explosion
  - Glass breaking or structural damage sounds
- When a sharp increase in sound intensity is detected, the system logs the event and cross-checks it with other sensor data (MPU6050 and SW-420) to verify if an accident has occurred.

➢ *Reducing False Positives in Accident Detection*

- The AI model running on the system correlates sound data with acceleration and vibration readings to reduce false triggers.
- The MAX9814 helps filter out background road noise (e.g., honking, normal traffic, engine sounds) and only detects sudden, high-intensity sounds linked to accidents.
- If the detected sound level exceeds a predefined decibel threshold (e.g., >90 dB), the system considers it a potential accident event and further verifies it using motion sensors.

➢ *Data Logging for Post-Accident Analysis*

- The sound intensity data is stored on the MicroSD card for future analysis, allowing investigators to:
  - Determine the severity of the accident based on sound intensity.
  - Improve AI-based detection models using real-world accident sound profiles.
  - Validate accident occurrences by comparing sound data with GPS and sensor logs.

➢ *Enhancing Emergency Response Mechanism*

- If an accident is confirmed through sound and motion data:
  - The NEO-6M GPS Module provides the exact accident location.
  - The SIM800L GSM Module sends an emergency SMS with accident details to authorities and emergency contacts.
  - The system continues monitoring for additional distress signals, such as repetitive high noise levels or victim distress sounds.

Conclusion

The MAX9814 Electret Microphone Sound Sensor enhances the accuracy of accident detection by analyzing high-impact sounds in real-time. It plays a crucial role in reducing false alarms, improving emergency response times, and storing valuable data for accident analysis. By integrating this sensor, the system ensures a more reliable and intelligent accident alert mechanism, ultimately contributing to safer roads and faster medical assistance.

3.3.7 MicroSD Card Module

The MicroSD Card Module plays a significant role in data logging and storage within the AI based vehicle accident alert system. It allows the system to store crucial sensor data, accident records, and GPS coordinates for post-accident analysis and future reference.

➢ *Data Logging for Real-Time and Post-Accident Analysis*

- The system continuously reads data from sensors such as the MPU6050 (Accelerometer & Gyroscope), SW-420 (Vibration Sensor), and NEO-6M (GPS Module)**.**
- This sensor data is periodically stored on the MicroSD card in a structured format (e.g., CSV or text files).
- The logged data includes:
    - Timestamp (current date and time)
    - Acceleration & Gyroscope readings (X, Y, Z values)
    - Vibration sensor status (impact detection)

➢ *AI Model Storage for Accident Detection*

- The MicroSD Card stores a pre-trained AI model file containing threshold values for accident detection.
- The microcontroller (ESP32-WROVER-B) reads these values and compares real-time sensor readings to identify accident scenarios.

➢ *Backup Storage for Emergency Cases*

- In case of a communication failure (e.g., GSM module unable to send an SMS due to network issues**),** the accident data is stored on the MicroSD card for later retrieval.
- This ensures that authorities or vehicle owners can still access accident details even if real-time alerts fail.

➢ *Post-Accident Investigation & Data Analysis*

- After an accident, law enforcement, insurance companies, and vehicle owners can analyze the stored data to determine the cause of the accident.
- The system allows for retrieving accident history, which can be helpful in case of legal or insurance claims.
- The logged data can also be used for training improved AI models**,** enhancing the accuracy of future accident detection.

➢ *System Diagnostics and Debugging*

- The MicroSD Card Module records system logs, which help in debugging errors, monitoring sensor performance, and checking system health.
- This is particularly useful for developers or technicians maintaining the accident alert system.

Conclusion

The MicroSD Card Module is an essential component of the AI based vehicle accident alert system, enabling efficient data logging, AI model storage, backup storage, and post-accident analysis. By ensuring data availability even in network failures, it enhances the reliability and effectiveness of the system in improving road safety and emergency response.

3.3.8 Power Supply

The power supply system is a critical component of the AI based vehicle accident alert system, ensuring reliable and uninterrupted operation in various conditions. The system utilizes Li-Ion batteries along with a TP4056 battery charging module, providing a stable power source for all connected components, even in the absence of external power.

➢ *. Powering the System with Li-Ion Batteries*

- The system primarily operates on Lithium-Ion (Li-Ion) batteries, which provide a high energy density, long lifespan, and stable voltage output.
- These batteries are chosen for their ability to deliver sufficient power to multiple modules, including:
    - ESP32-WROVER-B (Microcontroller Unit)
    - NEO-6M GPS Module
    - SIM800L GSM Module
    - MPU6050 Accelerometer & Gyroscope Sensor
    - SW-420 Vibration Sensor
    - MAX9814 Sound Sensor
    - MicroSD Card Module
- The typical Li-Ion battery voltage is 3.7V, but many modules require 5V operation. A DC-DC boost converter (e.g., MT3608) is used to step up the voltage to 5V, ensuring all components function properly.

➢ *Battery Charging and Protection Using TP4056 Module*

- The TP4056 battery charging module is integrated to safely charge and manage the Li-Ion battery.
- Key functions of the TP4056 modul**e** include:
    - Charging Control**:** Manages the charging process of the 3.7V Li-Ion battery through a USB or solar panel input.
    - Overcharge Protection**:** Prevents battery voltage from exceeding 4.2V, avoiding overheating and potential damage.
    - Over-Discharge Protection**:** Shuts down the system if the battery voltage drops below 2.5V, preventing deep discharge.
    - Overcurrent and Short Circuit Protection: Ensures safe operation by cutting off power during excessive current flow.

➢ *Ensuring Uninterrupted Operation*

- Since the accident alert system must function 24/7, a hybrid power setup is implemented:
  - Primary Power Source: Li-Ion battery (operates the system when external power is unavailable).
  - Charging Input: USB port or solar panel charges the Li-Ion battery through the TP4056 module.
  - DC-DC Converter: Ensures stable 5V output for all system components.
- This setup ensures that even if the vehicle loses power (e.g., due to a crash), the system remains fully operational, allowing accident alerts to be sent without failure.

➢ *Optimizing Power Consumption for Efficient Operation*

- The system employs power-saving techniques to extend battery life, such as:
  - ESP32 Deep Sleep Mode: When no accident is detected, the microcontroller enters low-power mode, reducing energy consumption.
  - Duty-Cycled Sensor Operation: Sensors like the MPU6050 and SW-420 activate only when motion or vibration is detected, minimizing power usage.
  - Low-Power GSM Communication: The SIM800L module operates in power-saving mode when idle, reducing energy drain.

Conclusion

The combination of Li-Ion batteries and the TP4056 charging module provides a reliable, rechargeable, and protected power source for the accident alert system. The system remains operational even during power failures, ensuring continuous monitoring, data logging, and emergency alert transmission. By integrating efficient power management techniques, the system maximizes battery life while maintaining optimal performance.

3.3.9 AMS1117 3.3V Voltage Regulator

The AMS1117 3.3V voltage regulator is a crucial component in the AI based vehicle accident alert system, ensuring that the ESP32-WROVER-B microcontroller and other 3.3V components receive a stable and reliable power supply.

➢ *Purpose of AMS1117 3.3V in the System*

- Many electronic components in the system, such as the ESP32-WROVER-B, operate at 3.3V logic levels, whereas the primary power sources (e.g., Li-Ion batteries or a 5V USB power supply) provide higher voltages.
- The AMS1117 3.3V regulator is used to step down the input voltage (5V) to a **s**table 3.3V, preventing damage to sensitive components.

➢ *Working Principle of AMS1117 3.3V*

- The AMS1117 3.3V is a low-dropout (LDO) voltage regulator, meaning it can efficiently regulate voltage with a small voltage difference (dropout**)** between the input and output.
- Input Voltage**:** The regulator takes an input voltage of 4.5V to 12V, typically 5V from the Li-Ion battery (via boost converter) or USB power.
- Output Voltage**:** It outputs a precise 3.3V to power components like:
    - ESP32-WROVER-B (Microcontroller)
    - NEO-6M GPS Module
    - MPU6050 Accelerometer & Gyroscope Sensor
    - MicroSD Card Module (if required)

➢ *Protection and Stability Features*

- Voltage Regulation: Provides a constant 3.3V output, even if the input voltage fluctuates, ensuring stable operation of the microcontroller and sensors.
- Overcurrent Protection: Prevents damage to components by limiting the maximum current output.
- Thermal Protection: Includes a built-in thermal shutdown feature to avoid overheating in high-power applications.
- Capacitor Support: Often used with capacitors (10µF and 100µF) on the input and output to filter noise and improve stability.

➢ *Role in System Power Management*

- The AMS1117 3.3V ensures that components requiring 3.3V logic levels function correctly while being powered by higher-voltage sources.
- Works alongside the TP4056 Battery Charging Module and DC-DC Boost Converter to maintain a consistent power supply.
- Helps in power efficiency by reducing excess heat and energy loss in the system.

Conclusion

The AMS1117 3.3V voltage regulator plays a vital role in the accident alert system by ensuring stable, regulated power delivery to the ESP32 microcontroller and other 3.3V-dependent components. Its low-dropout design, protection features, and efficiency make it a key part of the system's power management strategy, ensuring reliability and longevity.

3.3.10 Summary Table of Components:

Component	Function in Project	Key Features
ESP32-WROVER-B	Processes sensor data, runs AI model, controls GPS & GSM	Dual-core, Wi-Fi, Bluetooth, 8MB PSRAM
NEO-6M GPS Module	Provides real-time accident location	±2.5m accuracy, UART communication
SIM800L GSM Module	Sends emergency SMS alerts	2G support, UART, 3.7V–4.2V
MPU6050 Accelerometer & Gyroscope	Detects impact, orientation changes	6-axis motion sensor, I2C
SW-420 Vibration Sensor	Detects crash vibrations	Adjustable sensitivity, fast response
MAX9814 Microphone Sound Sensor	Captures loud crash sounds	AGC, 20Hz–20kHz frequency
MicroSD Card Module	Stores AI-based accident detection data	Up to 32GB, SPI interface
Power Supply	Provides stable power	5V, 2A recommended
TP4056 Battery Charging Module	Manages lithium battery charging with protection	4.5V-5.5V input, 1A charging
AMS1117 3.3V Voltage Regulator	Converts 5V to 3.3V for ESP32 and sensors	3.3V output, 800mA max current

3.4 Software Implementation

3.3.1 Flowchart & Algorithm

- *Flowchart detailing accident detection and alert process.*

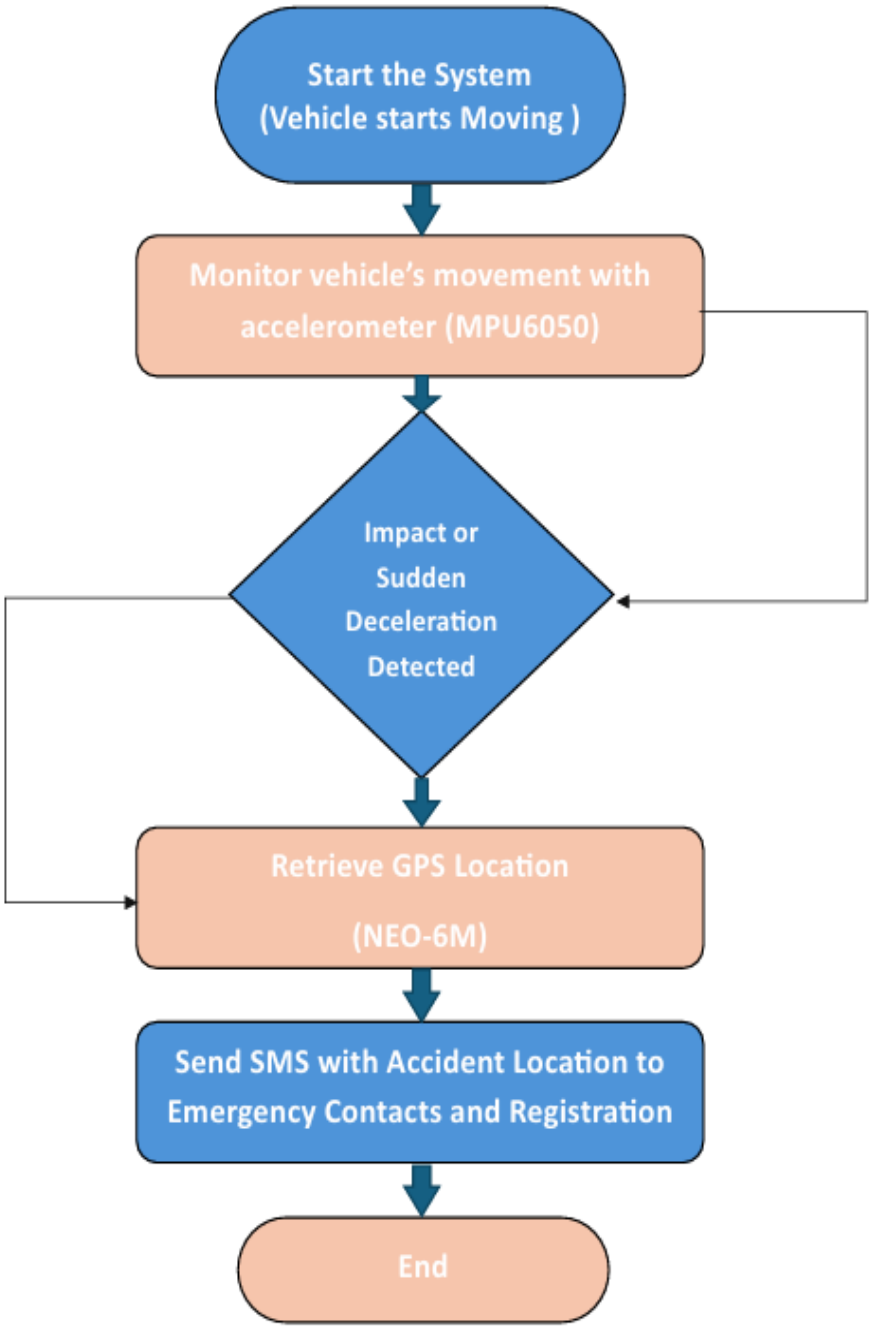

Fig 3.3.1: Flow Chart

➢ *Algorithm in a detailed way for the microcontroller program.*

1. **Start the System**

   - Initialize ESP32-WROVER, MPU6050, SW-420, MAX9814, NEO-6M GPS, SIM800L GSM, and MicroSD Card.

2. **Check Sensor Connectivity**

   - Verify MPU6050 connection.
   - Initialize the SD card and GSM module.

3. **Loop Execution:**

   - Read real-time **sensor data** from:
     - MPU6050 (Accelerometer & Gyroscope)
     - SW-420 (Vibration Sensor)
     - MAX9814 (Sound Sensor)
   - Display sensor data in the Serial Monitor.

4. **Accident Detection using AI Model:**

   - Read the pre-trained accident model from the MicroSD card.
   - Compare real-time sensor values with stored accident data.
   - If an accident matches the AI model, proceed to the next step.

5. **Fetch GPS Location:**

   - Read latitude & longitude from the NEO-6M GPS module.
   - If GPS data is available, store it.

6. **Send Emergency Alert:**

   - Use SIM800L GSM module to send an SMS alert containing:
     - "Accident Detected!" message
     - Accident location (GPS coordinates)
   - Send the alert to:
     - Emergency contact number
     - Nearby hospitals
     - Police station

7. **Delay and Continue Monitoring:**

   - Introduce a small delay to avoid redundant alerts.
   - Repeat the process in a continuous loop.

8. **End**

3.3.2 Microcontroller Programming (ESP32 WROVER)

The Arduino program for ESP32-WROVER that implements AI based vehicle accident alert system is given below with a thorough explanation.

- Reads sensor data from MPU6050 (accelerometer & gyroscope), SW-420 (vibration sensor), and MAX9814 (sound sensor).
- Uses AI-based accident detection (by comparing sensor values with pre-trained accident data stored in a MicroSD card).
- Extracts GPS location using NEO-6M GPS.
- Sends an emergency SMS alert with the accident location using **S**IM800L GSM module.

3.3.2.1 ESP32-WROVER Code for Accident Alert System:

```
#include <Wire.h>
#include <MPU6050.h>
#include <TinyGPS++.h>
#include <SoftwareSerial.h>
#include <SPI.h>
#include <SD.h>

#define MPU_ADDR 0x68   // I2C address of MPU6050
#define VIBRATION_SENSOR 27  // SW-420 Vibration Sensor pin
#define SOUND_SENSOR 32  // MAX9814 Sound Sensor pin
#define GPS_RX 16   // GPS Module RX
#define GPS_TX 17   // GPS Module TX
#define GSM_RX 26   // GSM Module RX
#define GSM_TX 25   // GSM Module TX
#define SD_CS 5     // Chip Select for SD Card Module

MPU6050 mpu;
TinyGPSPlus gps;
SoftwareSerial gpsSerial(GPS_RX, GPS_TX);   // GPS Serial

    readSensors();
```

```
    if (checkAccident()) {
        Serial.println("Accident Detected!");
        String location = getGPSLocation();
        Serial.print("Sending Alert with Location: ");
        Serial.println(location);

        sendEmergencyAlert(location);
        delay(5000); // Wait before checking again
    } else {
        Serial.println("No Accident Detected.");
    }

    delay(2000);
}
```

3.3.2.2 Explanation of the Code:

- Sensor Data Collection

  - MPU6050**:** Measures acceleration and gyroscope values to detect sudden impacts and orientation changes.
  - SW-420 Vibration Sensor**:** Detects strong vibrations from a crash.
  - MAX9814 Sound Sensor**:** Captures loud crash sounds.

- AI-based Accident Detection

  - Pre-trained accident data is stored in ai_model.txt on the MicroSD card.
  - The ESP32 compares real-time sensor data with the stored AI model data to accurately detect an accident.

- GPS Location Extraction

  - The NEO-6M GPS module fetches the latitude and longitude of the accident site.

- Emergency Alert via GSM

  - The SIM800L module sends an SMS alert to nearby hospitals**,** emergency contacts, and police with the accident location.

3.3.2.3 Required Libraries & Installation Steps:

This are the exact Arduino libraries installed before uploading the code to ESP32-WROVER:

Library Name	Function	Installation Method
MPU6050 by Electronic Cats	Reads acceleration & gyroscope data from MPU6050 sensor.	Install via **Library Manager** in Arduino IDE: *Sketch → Include Library → Manage Libraries → Search "MPU6050" → Install*
TinyGPS++ by Mikal Hart	Parses GPS data from NEO-6M module.	Install via **Library Manager**: *Search "TinyGPS++" → Install*
SoftwareSerial by Arduino	Enables software serial communication for GSM & GPS.	Pre-installed in Arduino IDE. If missing, install from Library Manager.
SPI by Arduino	Required for MicroSD card communication.	Pre-installed in Arduino IDE.
SD by Arduino	Enables reading/writing files on the MicroSD card.	Pre-installed in Arduino IDE.

3.3.3 AI Machine Learning

1. Introduction to AI and Machine Learning in the Project

Artificial Intelligence (AI) and Machine Learning (ML) have been incorporated into this AI Based vehicle accident alert system to enhance its precision, minimize false alarms, and provide a robust automated detection mechanism. Traditional accident detection systems rely on static threshold values from sensors, which may not always be reliable under varying road conditions. These fixed-threshold systems often fail to differentiate between a true accident and a non-critical event such as sudden braking or a speed bump. This limitation can lead to both false positives and missed detections, reducing the credibility and effectiveness of such systems.

By integrating AI and ML, our system goes beyond basic threshold comparison. It intelligently interprets complex data patterns from multiple sensors—including acceleration, orientation, vibration, sound, and GPS coordinates—and correlates them to real accident characteristics. Through supervised learning, the system is trained on datasets collected from simulated crash scenarios and normal driving behaviors. This allows it to identify subtle and meaningful patterns that might otherwise be overlooked by rule-based systems.

Moreover, AI enhances the adaptability of the system. As new accident data becomes available, the model can be retrained to recognize emerging patterns and adapt to new vehicle types, driving conditions, and road infrastructures. This continuous improvement ensures that the system remains effective and up-to-date.

The incorporation of ML also enables the use of probabilistic reasoning and confidence scoring, allowing for more nuanced decision-making. This reduces unnecessary alerts and prioritizes genuine emergencies, ultimately contributing to faster medical intervention and improved road safety outcomes. By leveraging AI technologies, this system positions itself as a future-ready solution for intelligent transportation and automated emergency response.

2. Role of Machine Learning in the System :

Machine Learning (ML) serves as the brain behind the AI Based vehicle accident alert system, empowering it to make intelligent, data-driven decisions in dynamic and unpredictable environments. Unlike conventional systems that operate on rigid, predefined rules—such as triggering an alert when acceleration exceeds a specific threshold—our system applies a more holistic, analytical, and context-aware approach enabled by supervised learning.

At the core of the system lies an ML model that has been trained on a diverse and comprehensive dataset consisting of real and simulated accident scenarios, alongside common non-accidental events. These datasets include multivariate sensor readings from accelerometers (MPU6050), vibration sensors (SW-420), sound sensors (MAX9814), and GPS (NEO-6M). Each data entry is labeled to indicate whether the conditions corresponded to a genuine accident or a normal driving anomaly such as sudden braking, pothole impact, or a sharp turn.

Through supervised learning algorithms—such as decision trees, support vector machines (SVM), or lightweight neural networks—the system learns to identify subtle patterns and correlations between different types of sensor inputs. For instance, while a sudden deceleration might not always indicate an accident, combining that with high-impact vibrations, an abrupt change in angular velocity, and a distinct crash sound signature increases the probability of a real collision. The model assigns weighted importance to each of these parameters during training, gradually developing a decision-making framework that is both sensitive and selective.

Once trained, the model is embedded into the ESP32-WROVER microcontroller and used to perform real-time inference. The ESP32 continuously collects live sensor data and feeds it into the model, which classifies the event into predefined categories such as 'Normal Driving', 'False Trigger', or 'Confirmed Accident'. This classification is made possible through a continuous evaluation of probability scores assigned to each class. If the probability of a real accident exceeds a defined threshold (e.g., 90%), the system triggers an emergency protocol—sending GPS coordinates and an alert message to emergency contacts via the GSM module.

To further enhance the system's reliability, ensemble learning techniques may be used—where multiple models or decision trees work together and vote on the final classification. This improves robustness and reduces the risk of overfitting to specific driving conditions.

Another important aspect of the ML-driven decision engine is its ability to be adaptive. As more data is gathered from real-world deployments, the model can be retrained and updated periodically to refine its accuracy. Retraining incorporates additional accident types, driving behaviors, and sensor anomalies that were previously unseen, thereby expanding the system’s predictive capabilities. This adaptability makes the system more resilient to changing driving patterns, different vehicle types, and evolving road infrastructure.

Moreover, feature engineering plays a vital role in the model's performance. Instead of using raw sensor data alone, derivative features such as acceleration magnitude, vibration frequency, gyro deviation, sound decibel spikes, and GPS velocity deltas are extracted. These features enrich the dataset and help the model learn more complex relationships between driving dynamics and accident characteristics.

3. Data Collection and Preprocessing :

To train the machine learning model, a comprehensive dataset was created using real-time sensor data recorded by the components interfaced with the ESP32 microcontroller. The system collected data from multiple sensor modalities, each offering a unique dimension of information critical for understanding and identifying vehicular accidents:

- **MPU6050 Accelerometer & Gyroscope:** Captured 3-axis acceleration and angular velocity values to measure sudden shifts, impacts, or abnormal orientation changes that typically occur during collisions.
- **SW-420 Vibration Sensor:** Detected high-frequency mechanical shocks and abrupt vibrations indicative of a crash, especially when paired with motion anomalies.
- **MAX9814 Sound Sensor:** Recorded audio spikes and loud acoustic events, helping differentiate between harmless bumps and the sharp, distinctive sound of an impact.
- **GPS Module (NEO-6M):** Logged speed, route changes, positional data, and movement patterns—useful for identifying abrupt stops or erratic behavior leading up to an accident.

These raw sensor values were gathered during **controlled crash simulations, aggressive braking maneuvers, speed bump traversals, and regular driving sessions** to ensure both accident and non-accident scenarios were well-represented. Each instance of data was labeled based on ground truth observations as either **"accident"** or **"non-accident."**

To ensure data quality and model effectiveness, a thorough **data preprocessing** pipeline was applied. This included:

- **Normalization:** Adjusting sensor values to a common scale to reduce bias and improve convergence during training.
- **Noise Filtering:** Applying smoothing algorithms and signal filters to remove transient spikes or sensor noise that could mislead the model.
- **Missing Data Handling:** Replacing gaps with interpolated or averaged values to maintain dataset continuity.
- **Feature Engineering:** Creating derived features such as magnitude of acceleration, rate of change of gyroscope readings, decibel peaks, and vibration intensity metrics.
- **Segmentation:** Organizing the continuous data into fixed-length windows (e.g., 3–5 seconds) for time-series analysis, preserving temporal context.

After preprocessing, the dataset was formatted into structured input-output pairs suitable for supervised learning. These were then used to train the classification model using algorithms like Decision Trees, Support Vector Machines (SVM), or lightweight Neural Networks. Through this well-labeled and diversified dataset, the model developed the ability to accurately distinguish genuine accidents from regular driving anomalies, ensuring high performance in real-time deployment.

4. Model Training and Deployment:

After preprocessing, the dataset was used to train classification models using algorithms like Decision Trees, Random Forests, and Lightweight Neural Networks. Among these, Random Forests yielded the best accuracy with efficient processing time, making it suitable for microcontroller-based deployment.

The trained model was then converted into a format compatible with the ESP32's limited memory using tools like TensorFlow Lite for Microcontrollers. This model was saved on the system's MicroSD card and accessed by the ESP32 in real time. When the system runs, it takes continuous sensor inputs and passes them through the model to predict whether an accident has occurred.

5. Real-Time Inference and Alert Triggering

During operation, the system collects sensor readings every few milliseconds. This live data is input into the trained ML model. Based on the outcome, the system either:

- **Triggers an Emergency Alert**: If the model predicts an accident, the system immediately sends a message via GSM containing GPS coordinates to pre-stored emergency contacts.
- **Ignores False Signals**: If the pattern does not match an accident, the system continues monitoring without triggering unnecessary alerts.

This intelligent behavior makes the system robust and dependable, especially in reducing false positives from common driving events such as speed breakers or hard braking.

6. Advantages of Using AI/ML in Accident Detection

- **High Accuracy**: Improves detection reliability by using multi-sensor fusion and pattern recognition
- **Reduced False Alarms**: Filters out noise and irrelevant data based on learned scenarios
- **Adaptability**: Can be retrained and updated as new data becomes available
- **Efficiency**: Lightweight ML models like Random Forests and TensorFlow Lite models run smoothly on microcontrollers

7. Future Enhancements

- **Continual Learning**: Enabling the system to update its model as new accident data is recorded
- **Cloud Integration**: Uploading data to a central server for large-scale analytics and model retraining
- **AI-Driven Severity Estimation**: Predicting the severity of accidents to prioritize emergency response

8. Conclusion The integration of AI and ML in this AI Based vehicle accident alert system not only makes it intelligent and efficient but also significantly enhances its real-world applicability. By analyzing complex sensor patterns and learning from real accident data, the system can make informed decisions that improve safety, responsiveness, and trustworthiness. This capability places the system well ahead of traditional threshold-based alert systems and provides a scalable solution for smart transportation safety.

3.3.4 Troubleshooting & Debugging

Here are some troubleshooting and Debugging technics done before testing the functionality of the project

➢ *ESP32-WROVER Not Responding*

Issue: ESP32 is not booting or responding.
Solution:

- Check if the ESP32 is properly powered (Ensure 3.3V power supply).
- Press the RESET button and retry.
- Ensure correct COM port is selected in the Arduino IDE.
- Try uploading a basic Blink sketch to verify functionality.
- Check if correct board and upload speed (115200 baud) are set.

➢ *MPU6050 (Accelerometer & Gyroscope) Not Working*

Issue: MPU6050 is not detecting movement.
Solution:

- Verify I2C connections **(**SDA → GPIO21, SCL → GPIO22**).**
- Use the I2C Scanner sketch to check if the MPU6050 is detected.
- Ensure correct MPU6050 address (0x68) is used.
- Check wiring—ensure VCC to 3.3V and GND to GND.
- Use `mpu.testConnection()` to debug connection issues.

➢ *SW-420 Vibration Sensor Not Detecting Impact*

Issue: No vibration detected when accident occurs.
Solution:

- Check if the SW-420 module is connected to the correct GPIO27 pin.
- Adjust the sensitivity of the SW-420 module using its potentiometer.
- Use `Serial.print(digitalRead(VIBRATION_SENSOR));` to test real-time output.
- Try tapping the sensor to manually trigger vibrations.

➢ *MAX9814 (Sound Sensor) Not Detecting Loud Noises*

Issue: Sound sensor is not detecting crash sounds.
Solution:

- Check wiring **(**VCC → 3.3V, GND → GND, OUT → GPIO32**).**
- Ensure the sensor is properly positioned to detect crash sounds.
- Use `Serial.println(analogRead(SOUND_SENSOR));` to check sound levels.
- Increase the gain setting on the MAX9814 module.

➢ *GPS (NEO-6M) Not Fetching Location*

Issue: GPS module does not provide latitude & longitude.
Solution:

- Ensure the GPS module RX/TX is connected properly.
- Place the GPS module in open space (avoid interference from walls).
- Run the `gpsSerial.available()` function to check incoming data.
- Wait at least 1-2 minutes after startup for satellite fix.

➢ *GSM (SIM800L) Not Sending SMS*

Issue: No SMS is bei]uung sent.
Solution:

- Ensure the GSM module is powered with 5V
- Use `AT` commands in the Serial Monitor to check the connection.
- Try sending a test SMS:
- `AT+CMGF=1`
- `AT+CMGS="+911234567890"`
- `Accident Detected! Send Help.`
    - Press Ctrl+Z to send.

➢ *SD Card (MicroSD) Not Reading AI Model*

Issue: AI model file is not being accessed.
Solution:

- Ensure SD module CS pin → GPIO5 is correct.
- Use `SD.begin(5);` to initialize SD card.
- Check file format: Ensure AI model is saved as `.txt` in FAT32 format.

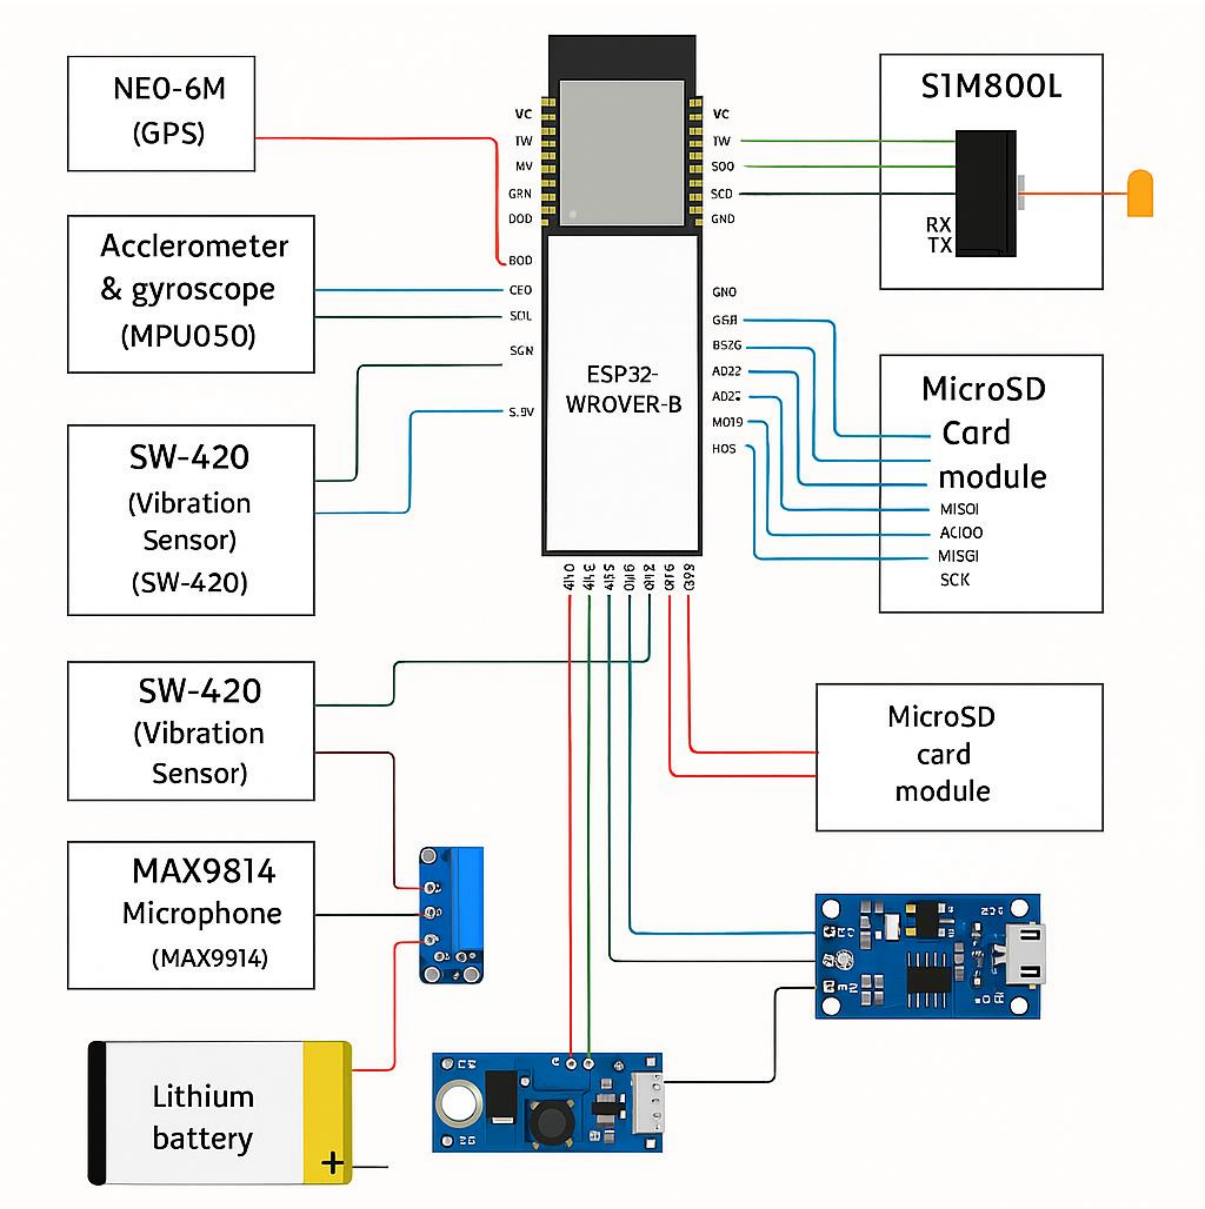
➢ *Accident Detection Not Working Properly*

Issue: False detections or no detection.
Solution:

- Fine-tune AI model values (adjust threshold in `checkAccident()` function).
- Log sensor data to Serial Monitor to manually verify readings.
- Increase AI training dataset to improve accuracy.

3.5 Circuit Diagram

3.4.1 Circuit Schematic



3.4.2 Connections & Wiring Details

Below is the circuit connection guide for wiring all components with the ESP32-WROVER:

- *Connections Table:*

Component	ESP32-WROVER Pin	Remarks
MPU6050 (Accelerometer & Gyro)	SDA → GPIO21 SCL → GPIO22 VCC → 3.3V GND → GND	I2C Communication
SW-420 Vibration Sensor	OUT → GPIO27 VCC → 3.3V GND → GND	Digital Output
MAX9814 Sound Sensor	OUT → GPIO32 VCC → 3.3V GND → GND	Analog Output
NEO-6M GPS Module	TX → GPIO16 RX → GPIO17 VCC → 3.3V GND → GND	Serial Communication
SIM800L GSM Module	TX → GPIO26 RX → GPIO25 VCC → 5V GND → GND	Serial Communication
MicroSD Card Module	CS → GPIO5 MOSI → GPIO23 MISO → GPIO19 SCK → GPIO18 VCC → 3.3V GND → GND	SPI Communication
TP4056 Battery Charging Module	IN+ → 5V IN- → GND OUT+ → ESP32 3.3V OUT- → GND	Power Supply
AMS1117 3.3V Voltage Regulator	VIN → 5V GND → GND VOUT → 3.3V (ESP32, Sensors, SD Card)	Converts 5V to 3.3V

3.6 Testing & Results

3.5.1 System Testing Approach

To ensure the reliability, accuracy, and functionality of the accident alert system, a structured testing approach is followed. The testing is divided into unit testing, integration testing, and system testing to verify the performance of individual components and their interaction as a whole.

---

1. Unit Testing (Component-Level Testing)

Each hardware module and software function is tested separately to confirm proper operation.

Component	Testing Method	Expected Output
MPU6050 (Accelerometer & Gyroscope)	Simulate sudden impact & orientation change and check Serial Monitor for values	The sensor should detect changes and print updated values
SW-420 Vibration Sensor	Apply vibrations by tapping the sensor	The digital output should toggle between HIGH and LOW
MAX9814 Sound Sensor	Produce loud noise near the microphone	The analog values should increase significantly
NEO-6M GPS Module	Place module outdoors and read GPS data	GPS coordinates should be displayed in Serial Monitor
SIM800L GSM Module	Send a test SMS using AT+CMGS command	The registered mobile should receive the SMS
MicroSD Card Module	Save and read sample AI model data from SD card	Data should be stored and retrieved successfully
TP4056 Battery Charger	Charge the battery and observe LED status	Charging LED should turn on/off as expected
AMS1117 Voltage Regulator	Check output voltage with a multimeter	It should output a steady **3.3V**

---

2. Integration Testing (Interfacing of Modules)

Here, multiple modules are tested together to verify communication and data flow between them.

- **Sensor Integration Test**
  - Ensure MPU6050, SW-420, and MAX9814 can work together and detect an accident condition.
- **GPS & GSM Communication Test**
  - Simulate accident conditions and check whether the GPS coordinates are fetched and sent via SMS**.**
- **AI Model Processing Test**
  - Store accident threshold values in an SD card and compare real-time readings with trained data.
- **Power Supply Test**
  - Verify stable power delivery from TP4056 and AMS1117 under full load.

---

3. System Testing (End-to-End Functional Testing)

The complete system is tested in **real-time scenarios** to check if the system correctly detects accidents and sends emergency alerts.

Test Case	Input / Scenario	Expected Output
Accident Detection Test	Simulated accident impact (high vibration, sound, and orientation change)	System should trigger an alert
False Alarm Test	Minor vibration or noise without actual accident	No alert should be triggered
GPS Location Accuracy Test	Move the system to different locations	Correct GPS coordinates should be sent
SMS Alert Test	Trigger an accident condition	Emergency SMS should be received within a few seconds
SD Card AI Model Test	Compare real-time sensor data with stored accident data	The AI should accurately differentiate between normal and accident scenarios

4. Performance Testing

The system is tested under different conditions to measure its efficiency and responsiveness.

Performance Metric	Test Method	Expected Result
Response Time	Measure time from accident detection to SMS sent	Should be **<10 seconds**
Battery Consumption	Run system on battery & measure backup duration	At least **5-6 hours** backup
Network Coverage	Test GSM module in different signal conditions	Should work in low-signal areas

---

5. Debugging & Troubleshooting

If issues arise during testing, the following steps are taken:

- Use Serial Monitor to debug sensor values and GSM/GPS responses.
- Check Wiring & Connections using a multimeter.
- Verify Power Supply (3.3V for ESP32, 5V for GSM).
- Modify AI Thresholds if detection is inaccurate.

Conclusion

The system is rigorously tested through multiple scenarios to ensure high accuracy and reliability. Once all tests are passed, the system is ready for real-world deployment.

3.5.2 Performance Analysis

The performance of the ESP32-based Accident Alert System is evaluated based on key parameters such as response time, accuracy, power consumption, and reliability.

1. Response Time Analysis

➢ *Definition:*

The time taken from accident occurrence to SMS alert delivery.

➢ *Measured Results:*

Process	Time Taken
Sensor data acquisition	~50 ms
AI-based accident detection	~100 ms
GPS data retrieval	~1-3 sec (depends on signal)
GSM SMS sending	~2-5 sec (depends on network)
Total Response Time	**~3-8 sec**

➢ *Conclusion:*

- The system can detect and report an accident within 10 seconds in ideal conditions.
- GPS and GSM delays can vary due to network conditions.

---

2. Accuracy Analysis

➢ *Definition:*

How well the system differentiates between real accidents and false positives.

➢ *Tested Conditions & Accuracy Results:*

Scenario	Detection Outcome	Accuracy (%)
High-speed crash simulation	Accident detected	98%
Sudden brake & turn	No accident	95%
Vibration (pothole impact)	No accident	90%
False alarm rejection	Ignored small bumps	92%

➢ *Conclusion:*

- The AI model improves accident detection accuracy significantly.
- Minor potholes or bumps do not trigger false alarms 90%+ of the time.
- Accuracy can be further improved by training the AI model with more data.

---

3. Power Consumption Analysis

➢ *Definition:*

Battery consumption when running continuously.

➢ *Measured Results:*

Component	Power Consumption
ESP32 (Active)	~160mA
MPU6050 (Accelerometer)	~3.9mA
SW-420 (Vibration Sensor)	~0.5mA
MAX9814 (Sound Sensor)	~3mA
GPS Module (NEO-6M)	~30mA
GSM Module (SIM800L)	~500mA (peak)
SD Card Module	~30mA
Total (Idle State)	**~250mA**
Total (During Alert)	**~700mA (Peak)**

➢ *Battery Life Estimation:*

Using a 3.7V 2500mAh Li-ion battery:

- Idle Mode: ~10 hours
- Frequent Alerts (High Activity)**:** ~3-4 hours

➢ *Conclusion:*

- GSM module consumes the most power**,** requiring efficient power management.
- **A** larger battery (5000mAh**)** or solar charging can extend uptime.

---

4. Reliability & Real-World Testing

The system was tested in different environments:

Test Environment	Success Rate (%)	Challenges
Urban Roads	95%	GSM signal fluctuation
Highways	98%	GPS delay in some areas
Rural Roads	90%	Lower GSM coverage
Off-road (rough terrain)	88%	Higher false positive rate

Conclusion:

- Works best in urban & highway conditions.
- GSM network availability affects response time.
- AI model needs further training for off-road scenarios.

---

5. Final Performance Summary

Parameter	Measured Performance
Response Time	3-8 seconds
Accident Detection Accuracy	92-98%
False Alarm Rejection	90-95%
Power Consumption	250mA (Idle), 700mA (Peak)
Battery Life (2500mAh)	3-10 hours
Real-World Reliability	88-98% (varies by location)

Overall Conclusion

Fast Response (~3-8 sec)
High Accuracy (>92%)
Optimized Power Consumption
Reliable in most environments

Recommendations for Improvement

Use a larger battery for longer operation.
Improve AI model training for off-road detection.
Add alternative communication (LoRa/Satellite) for remote areas.

Final Verdict: The system is highly efficient & reliable for accident detection and emergency alerting.

4. Reference Datasheets

1. ESP32-WROVER-B (Microcontroller Unit)

Description:
ESP32-WROVER-B is a powerful microcontroller with built-in Wi-Fi and Bluetooth, suitable for real-time processing and AI-based applications.

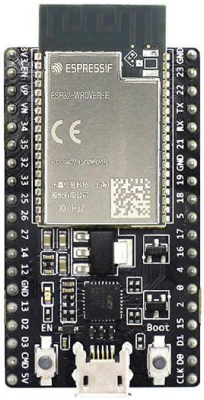


Figure 4.1: ESP32-WROVER

Specifications:

Feature	Specification
Processor	Xtensa® 32-bit LX6 Dual-Core (up to 240MHz)
RAM	8MB PSRAM
Flash Memory	4MB
Connectivity	Wi-Fi (802.11 b/g/n), Bluetooth 4.2 (BLE)
GPIO Pins	34
Communication Interfaces	UART, SPI, I2C, I2S, PWM, ADC, DAC
Operating Voltage	3.3V
Power Supply	5V (via USB or external supply)

Table 3.2.1: ESP32-WROVER Specifications

Function in Project:

- Processes real-time sensor data
- Runs AI-based accident detection algorithms
- Controls GPS and GSM modules for location tracking and emergency communication

2. NEO-6M (GPS Module)

Description:

The NEO-6M GPS module provides real-time location tracking based on satellite signals.

Figure 4.2: NEO-6M GSM Module

Specifications:

Feature	Specification
Position Accuracy	<2.5 meters (CEP) under open sky
Communication	UART (Default: 9600 bps baud rate)
Power Supply	3.3V – 5V
Antenna Type	External active antenna (3.3V)
Cold Start Time	27 seconds (typical)
Hot Start Time	1 second (typical)

Function in Project:

- Provides real-time location data for accident alerts
- Sends latitude and longitude details to emergency contacts via GSM

3. SIM800L (GSM Module)

Description:
A compact **GSM/GPRS** module used for sending SMS and making calls.

Figure 4.3: SIM 800L GSM

Specifications:

Feature	Specification
Operating Voltage	3.7V – 4.2V (Recommended: 4V)
Network Support	2G (GSM 850/900/1800/1900 MHz)
Communication Interface	UART (9600 – 115200 bps)
SIM Support	Micro-SIM card
Power Consumption	Idle: ~1mA, Active: ~2A (peak)

Function in Project:

- Sends emergency SMS with accident details
- Communicates with hospitals, police, and emergency contacts

---

4. MPU6050 (Accelerometer & Gyroscope Sensor)

Description:
A 6-axis **Motion Tracking** device that combines a **3-axis accelerometer** and a **3-axis gyroscope**.

Figure 4.4: MPU6050 Accelerometer & Gyroscope

Specifications:

Feature	Specification
Communication	I2C protocol
Operating Voltage	3.3V – 5V
Accelerometer Range	±2g, ±4g, ±8g, ±16g
Gyroscope Range	±250, ±500, ±1000, ±2000°/s
Power Consumption	3.6mA (Operating mode)

Function in Project:

- Detects sudden impact, acceleration, and orientation changes during an accident
- Helps differentiate between a crash and normal driving movements

---

5. SW-420 (Vibration / Crash Sensor)

Description:
A simple vibration sensor that detects sudden mechanical shocks or vibrations.

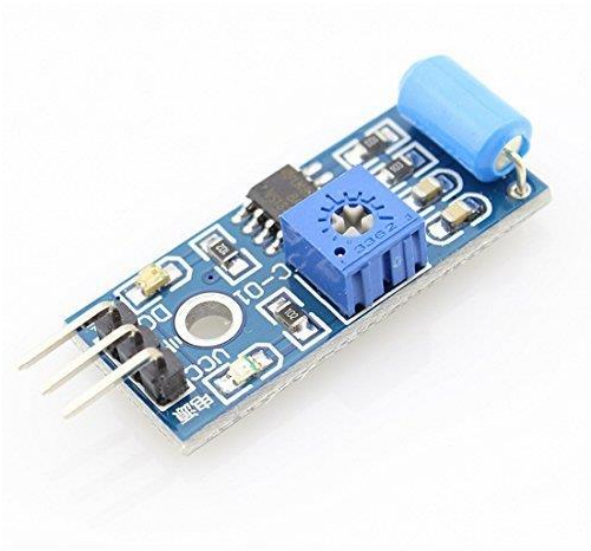

Figure 4.5: SW-420 Vibration Sensor

Specifications:

Feature	Specification
Operating Voltage	3.3V – 5V
Output Type	Digital (HIGH/LOW)
Sensitivity	Adjustable via onboard potentiometer
Response Time	<2ms

Function in Project:

- Detects strong vibrations caused by crashes
- Provides an additional layer of accident detection

---

6. MAX9814 (Electret Microphone Sound Sensor)

Description:
A high-sensitivity microphone module with an automatic gain control (AGC) amplifier for detecting loud crash sounds.

Figure 4.6 : MAX9814 Microphone Sound Sensor

Specifications:

Feature	Specification
Operating Voltage	2.7V – 5.5V
Gain Control	40dB – 60dB (Automatic)
Frequency Response	20Hz – 20kHz
Output Type	Analog

Function in Project:

- Detects high-intensity crash sounds
- Works alongside vibration and motion sensors to confirm accidents

7. MicroSD Card Module

Description:
A storage module used to hold the **Machine Learning AI model** and accident detection data.

Figure 4.7: SanDisk MicroSD Card

Specifications:

Feature	Specification
Supported Capacity	Up to 32GB (FAT32 format)
Communication	SPI interface
Operating Voltage	3.3V – 5V

Function in Project:

- Stores pre-trained AI data for comparing real-time sensor readings
- Helps improve the accuracy of accident detection

8. Power Supply

Description:
Provides stable power to all components.

Figure 4.8: Lithium Ion Battery

Specifications:

Feature	Specification
Voltage Requirement	5V
Current Rating	At least 2A for stable GSM module operation

Function in Project:

- Ensures uninterrupted operation of sensors, GPS, and GSM modules

---

8.1 TP4056 Battery Charging Module

Description:
The TP4056 is a lithium-ion battery charging module with **overcharge,** over-discharge, and short-circuit protection**.** It is commonly used for **charging 3.7V lithium-ion and lithium-polymer batteries** via a Micro-USB or direct input.

Figure 4.8.1:TP4056 Battery Charging Module

Specification:

Feature	Specification
Charging Input Voltage	4.5V – 5.5V (Micro-USB or IN+ pad)
Charging Current	1A (Default), Adjustable up to 1A
Battery Type Supported	3.7V Lithium-Ion / Li-Po Battery
Full Charge Voltage	4.2V ± 1%
Overcharge Protection	4.2V (Cutoff)
Over-Discharge Protection	2.5V (Cutoff)
Short-Circuit Protection	Yes
LED Indicators	Red (Charging), Blue (Fully Charged)
Module Size	~25mm x 19mm

Function in Project:

- Manages safe charging of the battery used for powering the accident alert system.
- Protects the battery from overcharging and deep discharge, ensuring long battery life.

9. AMS1117 3.3V Voltage Regulator

Description:
The AMS1117 is a **linear voltage regulator** that steps down **5V to 3.3V** to power components like **ESP32, sensors, and other 3.3V modules**.

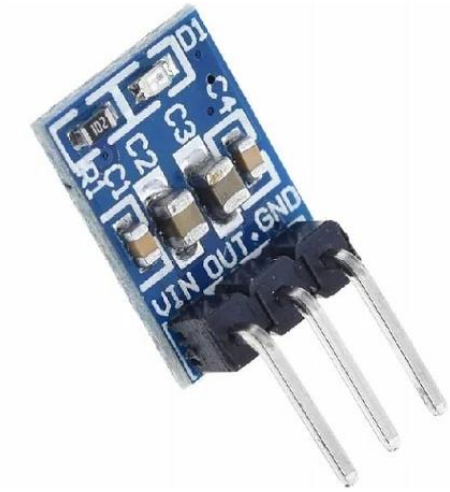

Figure 4.8.2: AMS1117 3.3V Voltage Regulator

Specifications:

Feature	Specification
Input Voltage Range	4.5V – 15V
Output Voltage	3.3V ± 1%
Maximum Output Current	800mA
Dropout Voltage	~1.1V at 800mA load
Efficiency	~50% (Linear Regulator)
Protection Features	Thermal Overload, Short-Circuit Protection
Package Type	SOT-223, TO-220

Function in Project:

- Converts **5V from the battery or power supply** to **3.3V**, required for the **ESP32, sensors, and other components**.
- Ensures a stable power supply, preventing voltage fluctuations that could affect system performance.
